## 54/74167 <br> SYNCHRONOUS DECADE RATE MULTIPLIER

DESCRIPTION - The '167 contains a synchronous decade counter and four decoding gates that serve to gate the clock through to the output at a submultiple of the clock frequency. The output pulse rate, relative to the clock frequency, is determined by signals applied to the Select ( $S_{0}-S_{3}$ ) inputs. Both true and complement outputs are available, along with an enable input for each. A Count Enable input and a Terminal Count output are provided for cascading two or more packages. Asynchronous Master Reset and Master Set inputs prevent counting and clear the counter or set it to maximum, respectively.

ORDERING CODE: See Section 9

1. This is a simplified illustration of the clear function. $C P$ and $\bar{E}_{Z}$ also affect the logic level of $O_{Y}$ and $\overline{\mathrm{O}}_{z}$. A LOW signal on Ey will cause Oy to remain HIGH.
2. Each rate illustrated assumes $S_{0}-S_{3}$ are constant throughtout the cycle; however, these illustrations in no way prohibit variable-rate operation.
3. These input condtions exceed the range of the decade rate Select inputs.
4. EY can be used to inhibit output $\mathrm{O}_{\mathrm{Y}}$.

L = LOW Voltage Level

FUNCTIONAL DESCRIPTION - The ' 167 contains four JK flip-flops connected as a synchronous decade counter with a count sequence of 0-1-2-3-4-8-9-10-11-12. A LOW signal on the Count Enable $\bar{C} \overline{C E})$ input permits counting, with all state changes initiated simultaneously by the rising edge of the clock. When the count reaches maximum (12) the Terminal Count ( $\overline{\mathrm{TC}}$ ) output goes LOW if $\overline{\mathrm{CE}}$ is LOW. A HIGH signal on Master Reset (MR) clears the flip-flops and prevents counting, although output pulses can still occur if the clock is running, $\bar{E}_{2}$ is LOW and $\mathrm{S}_{3}$ is HIGH. A HIGH signal on Master Set (MS) prevents counting and sets the counter to 12, the only state in which no output pulses can occur.

The flip-flop outputs are decoded by a 4-wide AND-OR-INVERT gate. Each AND gate also contains the buffered and inverted CP and $Z$-enable ( $\bar{E}_{Z}$ ) functions, as well as one of the Select ( $S_{0}-S_{3}$ ) inputs. The $Z$ output $\bar{O}_{Z}$ is normally HIGH and goes LOW when CP and $\bar{E}_{Z}$ are LOW and any of the AND gates has its other inputs HIGH. The AND gates are enabled at different times and different rates relative to the clock. For example, the gate to which $\mathrm{S}_{0}$ is connected is enabled only when the counter is in state five, assuming that $\mathrm{S}_{0}$ is HIGH. Thus, during one complete cycle of the counter ( 10 clocks) the $\mathrm{S}_{0}$ gate can contribute only pulse to the output rate. The $\mathrm{S}_{1}$ gate is enabled twice per cycle, the $\mathrm{S}_{2}$ gate four times per cycle(etc.). The output pulse rate thus depends on the clock rate and which of the $\mathrm{S}_{0}-\mathrm{S}_{3}$ inputs are HIGH, as expressed in the following formula.

$$
\begin{gathered}
f_{\text {out }}=\frac{m}{10} \bullet \text { fin } \\
\text { where } m=S_{3} \bullet 2^{3}+S_{2} \bullet 22+S_{1} \bullet 21+S_{0} \bullet 20
\end{gathered}
$$

Thus by appropriate choice of signals applied to the $\mathrm{S}_{0}-\mathrm{S}_{3}$ inputs, the output pulse rate can range from $1 / 10$ to $9 / 10$ of the clock rate. The select codes, $m$ values and $\bar{O}_{z}$ pulse pattern are shown in the Pulse Pattern Table. In the $\bar{O}_{z}$ pattern, each column represents a clock period, with the state- 12 column on the right. A one indicates that the $\overline{\mathrm{O}}_{z}$ output will be HIGH during that entire clock period, while a zero indicates that $\overline{\mathrm{O}}_{z}$ will be LOW when the clock is LOW during that period. Note that the output pulses are evenly spaced only when $m$ is one or two, assuming that the clock frequency is constant, and that no output pulses can occur in state 12 of the counter.

The $Y$ output $O_{Y}$ is the complement of $\bar{O}_{Z}$ and is thus normally LOW. A LOW signal on the Y -enable input $\mathrm{E}_{Y}$ disables Oy . To expand the multiplier to 2-digit rate select, two packages can be cascaded as shown in Figure a. Both circuits operate from the basic clock, with the $\overline{\text { TC }}$ output of the first acting to enable both counting and the output pulses of the second package. Thus the second counter advances at only $1 / 10$ the rate of the first and a full cycle of the two counters combined requires 100 clocks. Output pulses contributed by the second counter occur only when the first counter is in state 12. All output pulses are opposite in phase to the clock.
