| a-g | Segment Outputs (Active HIGH) | $0 / 6.25$ |

FUNCTIONAL DESCRIPTION - The '07 7-segment decoder accepts a 4-bit BCD 8421 code input and produces the appropriate outputs for selection of segments in a 7-segment matrix display used for representing the decimal numbers 0-9. The seven outputs ( $a, b, c, d, e, f, g$ ) of the decoder select the corresponding segments in the matrix shown in Figure a. The numeric designations chosen to represent the decimal numbers are shown in Figure b, together with the resulting displays for input code configurations in excess of binary nine.

The decoder has active HIGH outputs so that a buffer transistor may be used directly to provide the high currents required for incandescent displays. If additional base drive current is required external resistors may be added from the supply voltage to the seven segment outputs of the decoders. If additional base drive current is required external resistors may be added from the supply voltage to the seven segment outputs of the decoders. The value of this resistor is constrained by the 10 mA current sinking capability of the output transistors of the circuit.

The device has provision for automatic blanking of the leading and/or trailing-edge zeroes in a multidigit decimal number, resulting in an easily readable decimal display conforming to normal writing practice. In an eight digit mixed integer fraction decimal representation, using the automatic blanking capability, 0060.0300 would be displayed as 60.03 . Leading-edge zero suppression is obtained by connecting the Ripple Blanking Output ( $\overline{\mathrm{RBO}}$ ) of a decoder to the Ripple Blanking Input ( $\overline{\mathrm{RBI}}$ ) of the next lower stage device. The most significant decoder stage should have the $\overline{R B I}$ input grounded; and, since suppression of the least significant integer zero in a number is not usually desired, the $\overline{R B T}$ input of this decoder stage should be left open. A similar procedure for the fractional part of a display will provide automatic suppression of trailing-edge zeroes.

The decoder has an active LOW input Lamp Test which overrides all other input combinations and enables a check to be made on'possible display malfunctions. The $\overline{\text { RBO }}$ terminal of the decoder can be OR-tied with a modulating signal via an isolating buffer to achieve pulse duration intensity modulation. A suitable signal can be generated for this purpose by forming a variable frequency multivibrator with a cross coupled pair of TTL gates.
